

# Together Horizon: Command Center Writeup

Codebase: <https://github.com/SanatanSinghVishen/Together.git>

## 1. TOGETHERMIND - OPERATOR KNOWLEDGE ASSISTANT

### Core Concept & Purpose

TogetherMind is designed to capture, organize, and search the collective business experience of Together Fund's VC partners. When an early-stage startup founder is growing their company, they frequently face strategic hurdles, such as hiring their first sales managers, building marketing structures, or raising follow-on rounds. Instead of waiting for a scheduled sync with a partner, the founder can query TogetherMind. The AI reviews the partners' playbooks, essays, and direct advice to synthesize a cited, direct answer. This gives founders instant strategic support 24/7, preserving the partners' limited time for complex, high-stakes strategic reviews.

### Architectural Implementation

At its core, TogetherMind uses a local semantic Retrieval-Augmented Generation (RAG) ingestion pipeline. When a partner uploads a strategy playbook (TXT, MD, or PDF format), the document is split into overlapping text chunks of 800 characters. Each chunk is transformed into a 384-dimensional vector using local embedding functions ('all-MiniLM-L6-v2') and stored in a ChromaDB collection. When a user asks a question, the vector store retrieves the top 5 most relevant text chunks. The AI agent reviews the retrieved segments, identifies key recommendations, and synthesizes a direct answer with inline citations. If the question is highly subjective or sensitive (e.g. board seat conflicts, firing an executive, or legal disputes), it automatically triggers a GP Escalation Protocol, routing the ticket to a human partner and notifying the user.

---

## TOGETHER HORIZON - VENTURE INTELLIGENCE COMMAND DECK

### Founder & Partner Segregation

To make the workspace intuitive, the user interface has been segregated into two distinct roles. The 'Founder Desk' provides a clean console focused entirely on Q&A queries. The 'Investor Panel' provides partners with library status checkers, document counts, re-indexing buttons, and a drag-and-drop playbook uploader. In the backend, when a query is submitted, the formatter model uses a strict JSON schema (OperatorQueryResponse) to map outputs. If the query escalates, the system guarantees that the AI's explanation of why it escalated is displayed on the screen instead of being overwritten.

### Successes, Improvements & Production Requirements

Successes: The clear role segregation ensures founders see a clean consulting dashboard, while partners have an exclusive panel to upload files. The local vector embeddings run completely offline, reducing cost and latency.

Future Improvements: With more time, we would implement advanced layout-aware PDF parsers to handle structural text (like tables, bullet grids, or column divisions) inside complex business memos.

Production Needs: Direct database migration to a hosted cloud vector database (like Supabase pgvector or Pinecone) and integrations with internal partner emails and Slack logs to capture advice patterns dynamically.

## 2. SIGNAL - PORTFOLIO HEALTH TRIAGE

### Core Concept & Purpose

Signal is a portfolio health triage dashboard designed to streamline investor oversight. VC partners manage dozens of startups and cannot proactively check in on every founder every day. Signal solves this by reading short, weekly text logs submitted by portfolio founders. The AI automatically parses these logs to extract key growth metrics and founder stress levels, ranking the portfolio on a command dashboard so investors know exactly which company needs immediate, hands-on support.

---

## TOGETHER HORIZON - VENTURE INTELLIGENCE COMMAND DECK

### Architectural Implementation

Signal is built on a relational SQLite database schema (companies, updates, signals, and briefings). When a founder submits their weekly log, an AI analyzer extracts signals: revenue trend (Up, Flat, Down, Not Mentioned), raw metric details, hiring milestones, blockers, and founder sentiment. The triage engine compares these signals against the company's historical updates. By checking for persistent blockers or sudden drops in sentiment, it calculates an urgency score from 0.0 to 10.0 and applies prioritized labels (Critical, Warning, Stable), streaming the analysis to the dashboard.

### Successes, Improvements & Production Requirements

Successes: SQLite baseline tracking successfully catches negative developments early. The automated URL onboarding scraper allows partners to onboard new acquisitions simply by entering their website link, auto-extracting metadata.

Future Improvements: Build interactive metric charts on the dashboard to visualize revenue trends and sentiment shifts.

Production Needs: Direct API integrations with startups' backend metrics tools (such as Stripe for revenue or HubSpot for sales) to verify self-reported founder logs against live objective figures.

## 3. CORRIDOR COMPASS - GLOBAL READINESS AUDITOR

### Core Concept & Purpose

Corridor Compass is a GTM diligence auditor. Indian startups expanding into international markets often face compliance, pricing, and messaging barriers. Compass audits landing copy and structures against global benchmarks, providing a readiness score and developer fix tickets before they present to international clients.

---

## TOGETHER HORIZON - VENTURE INTELLIGENCE COMMAND DECK

### Architectural Implementation

Compass crawls landing page text using BeautifulSoup to clean copy. It coordinates three specialized AI critics in parallel (Messaging copy, Pricing structure, and Trust signals) and resolves conflicts using a lead editor agent. It supports target-country diligence, dynamically customizing prompts for local expectations (e.g. GDPR in Europe vs. SOC2 in the US). If pricing copy is missing on the homepage, it queries DuckDuckGo for the startup's subscription plans to prevent unfair score penalties.

### Successes, Improvements & Production Requirements

Successes: The target-country auditing and DDG pricing searches prevent false-negative ratings, yielding highly customized reports.

Future Improvements: Integrate visual screenshot analysis (multimodal LLM checks) to audit layout alignment, spacing, and design.

Production Needs: Standardized compliance rules vetted by GTM advisors to continuously update benchmark schemas.

## 4. CORE PRODUCTION HANDOVER REQUIREMENTS

To successfully launch the Together Horizon command deck into production, the following steps must be completed:

1. Migrate SQLite and ChromaDB from local files to hosted databases (e.g. Supabase, AWS RDS PostgreSQL) to support concurrent access.
2. Implement authentication (Cognito/Auth0) to isolate sensitive partner dashboards from startup founder views.
3. Configure enterprise LLM accounts with strict data privacy options, ensuring no playbook data is used to train public LLM models.
4. Setup cron triggers to ingest new playbooks and scan updates automatically.
