

Together Horizon: Command Center Technical Writeup

GitHub Codebase: <https://github.com/SanatanSinghVishen/Together.git>

1. TOGETHERMIND - OPERATOR KNOWLEDGE ASSISTANT

Core Concept & Purpose

TogetherMind is built to centralize and share the business building experience of Together Fund's VC partners. When an early-stage startup founder is growing their company, they frequently face strategic hurdles, such as hiring their first sales managers, building marketing structures, or raising follow-on rounds. Instead of waiting for a scheduled sync with a partner, the founder can query TogetherMind. The AI reviews the partners' playbooks, essays, and direct advice to synthesize a cited, direct answer. This gives founders instant strategic support 24/7, preserving the partners' limited time for complex, high-stakes strategic reviews.

Architectural Implementation & Segregation

At its core, TogetherMind uses a local semantic Retrieval-Augmented Generation (RAG) ingestion pipeline. Custom playbooks uploaded by partners are split into overlapping 800-character chunks, vectorized using local embeddings ('all-MiniLM-L6-v2'), and stored in ChromaDB. On query, ChromaDB retrieves the top 5 relevant text segments. The AI agent reviews the segments, synthesizes a direct answer with citations, and routes subjective queries to a human GP via the Escalation Protocol. To make the workspace intuitive, the user interface is segregated into a 'Founder Desk' for Q&A queries and an 'Investor Panel' for database checkups, re-indexing, and playbook uploading. The backend JSON formatter preserves GP escalation notes so they are never overwritten with 'none'.

Successes, Future Improvements & Production Requirements

The clear role segregation successfully limits partner admin overhead while delivering instant guidance. Local vector databases run completely offline with zero hosting costs, reducing latency. Future improvements include layout-aware PDF parsers to handle memos tables. For production, we require direct migration to a hosted cloud vector database (like Supabase pgvector) and Slack integration to ingest partner advice logs dynamically.

2. SIGNAL - PORTFOLIO HEALTH TRIAGE

Core Concept & Purpose

Signal is a portfolio health triage dashboard designed to streamline investor oversight. VC partners manage dozens of startups and cannot proactively check in on every founder every day. Signal solves this by reading short, weekly text logs submitted by portfolio founders. The AI automatically parses these logs to extract key growth metrics and founder stress levels, ranking the portfolio on a command dashboard so investors know exactly which company needs immediate, hands-on support.

Architectural Implementation & Metrics Sync

Signal is built on a relational SQLite database schema (companies, updates, signals, and briefings). When a founder submits their weekly log, an AI analyzer extracts signals: revenue trend (Up, Flat, Down, Not Mentioned), raw metric details, hiring milestones, blockers, and founder sentiment. The triage engine compares these signals against the company's historical updates. By checking for persistent blockers or sudden drops in sentiment, it calculates an urgency score from 0.0 to 10.0 and applies prioritized labels (Critical, Warning, Stable), streaming the analysis to the dashboard. The metrics are synchronized in SQLite, allowing partners to onboard new acquisitions simply by entering their website link to auto-scrape metadata.

Successes, Future Improvements & Production Requirements

SQLite baseline tracking successfully catches negative developments early. The automated URL onboarding scraper allows partners to onboard new acquisitions simply by entering their website link. Future improvements include interactive metrics charts to visualize revenue trends and sentiment shifts on the workspace. For production, we require direct API integrations with startups' backend metrics tools (such as Stripe for revenue or HubSpot for sales) to verify logs against live objective figures.

3. CORRIDOR COMPASS - GLOBAL READINESS AUDITOR

Core Concept & Purpose

Corridor Compass is a GTM diligence auditor. Indian startups expanding into international markets often face compliance, pricing, and messaging barriers. Compass audits landing copy and structures against global benchmarks, providing a readiness score and developer fix tickets before they present to international clients.

Architectural Implementation & Critic Pipeline

Compass crawls landing page text using BeautifulSoup to clean copy. It coordinates three specialized AI critics in parallel (Messaging copy, Pricing structure, and Trust signals) and resolves conflicts using a lead editor agent. It supports target-country diligence, dynamically customizing prompts for local expectations (e.g. GDPR in Europe vs. SOC2 in the US). If pricing copy is missing on the homepage, it queries DuckDuckGo for the startup's subscription plans to prevent unfair score penalties. Each critic runs as an independent context-bound agent. The Messaging Critic checks for value clarity, the Pricing Critic evaluates tier transparency, and the Trust Signals Critic scans for compliance badges, outputting a prioritized fix checklist.

Successes, Future Improvements & Production Requirements

The target-country auditing and DDG pricing searches prevent false-negative ratings, yielding highly customized reports. Future improvements include visual screenshot analysis (multimodal LLM checks) to audit layout alignment, spacing, and design. For production, we require standardized compliance checklists vetted by international GTM advisors to continuously update reference benchmarks.

4. CORE PRODUCTION HANDOVER & READINESS REQUIREMENTS

To successfully transition the Together Horizon command center from local staging to a secure, production-grade corporate asset, the following structural dependencies must be provided by the firm:

1. Central Database Migration

Migrate SQLite and ChromaDB from local files to a hosted, high-availability data infrastructure (such as AWS RDS PostgreSQL with pgvector, or Supabase). This resolves file locking, supports concurrent connections from multiple partners, and ensures long-term persistent storage across server scale-outs and restarts.

2. Enterprise Authentication Gateways

Integrate token-based Identity Providers (such as Auth0, AWS Cognito, or Okta SSO) with role-based access control (RBAC). This enforces access isolation between public founder desks and sensitive partner triage boards.

3. Secure Enterprise LLM Configuration

Establish private enterprise agreements with LLM providers (e.g. OpenRouter/Google/OpenAI) with strict data privacy clauses. This guarantees that proprietary VC operating playbooks, emails, and sensitive startup metrics are never logged or utilized to train public model checkpoints.

4. Automated Data ingestion Scanners

Set up background task runners (such as Celery with Redis or AWS Lambda crons) to automate weekly founder updates ingestion and playbook vector updates, removing the need for manual, local terminal triggers.
